

Chronic Kidney Disease Monitoring Standard

Source: Neuron Renal Care Standards

Baseline testing

Assess renal function with serum creatinine and estimated glomerular filtration rate. Confirm any abnormal result with a repeat sample within two weeks before assigning a chronic kidney disease stage.

Albuminuria

Measure the urine albumin to creatinine ratio on an early morning sample. A ratio above 3 milligrams per millimole is significant and should be confirmed on a second sample.

Medication review

Review ACE inhibitors, angiotensin receptor blockers, diuretics, and non-steroidal anti-inflammatory drugs when renal function declines. Check potassium and creatinine one to two weeks after a dose change.

Escalation

An estimated glomerular filtration rate below 30 millilitres per minute, a sustained fall of more than 25 percent, or potassium above 6.0 millimoles per litre needs urgent nephrology discussion.
