

Inflammatory Marker Assessment

Source: Neuron Diagnostics Library

Context

Interpret C-reactive protein and erythrocyte sedimentation rate alongside the clinical picture. Neither marker is diagnostic on its own.

Persistent elevation

Investigate a persistently raised C-reactive protein with a full blood count, renal and liver profile, and imaging guided by symptoms.

Escalation

A C-reactive protein above 100 milligrams per litre with fever or haemodynamic instability suggests serious infection and needs immediate review.

Documentation

Record the suspected source and the planned reassessment interval whenever an inflammatory marker is abnormal.
